

## CONCEPT: LIGHT INDEPENDENT REACTIONS (CALVIN CYCLE)

### Carbon Fixation (Calvin Cycle)

- **Carbon fixation** uses ATP and NADPH to fix carbon from  $\text{CO}_2$  in order to create sugar in  $\text{C}_3$  plants (majority of plants)
  - $\text{CO}_2$  is attached to ribulose 1,5 biphosphate (5 carbon sugar)
    - Creates two 3-phosphoglycerates (two three carbon sugars) (Step 1)
    - Reduced to form glyceraldehyde 3-phosphate (Step 2)
    - Releases  $\text{O}_2$  as \_\_\_\_\_ product
  - **RUBISCO** (ribulose biphosphate carboxylase) catalyzes carbon fixation
    - Works slowly – so plants need a lot of it (most abundant protein on earth)
  - ATP and NADPH are used to generate more ribulose 1,5 biphosphate (Step 3)
  - 3  $\text{CO}_2$  makes one glyceraldehyde 3-phosphate \_\_\_\_\_ 9 ATP and 6 NADPH

### **EXAMPLE:** Overview of the Calvin Cycle

- Once the glyceraldehyde 3-phosphate is created it can be used in a number of ways
  - Converted into starch
  - Used in glycolysis to create ATP
  - Made into sucrose or other sugars

### Carbon Fixation in C4 and CAM Plants

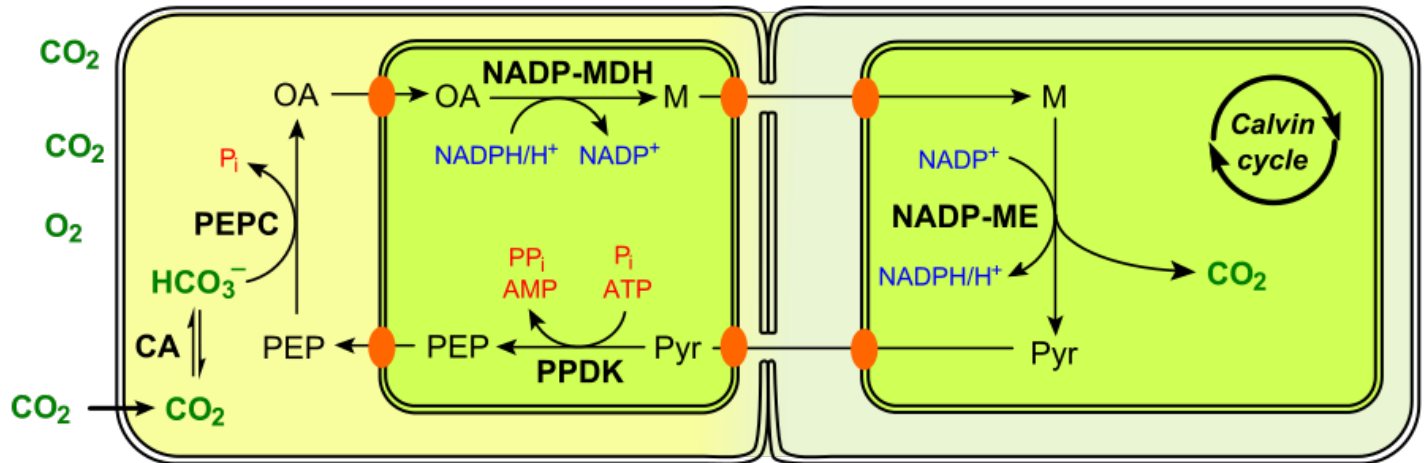

- Carbon fixation that occurs in C3 plants (most plants) is not efficient in \_\_\_\_\_ environments
  - **Stroma** (pores) in the plant leaves \_\_\_\_\_ when its hot to prevent loss of water
    - Unfortunately, this prevents gas exchange (entering of CO<sub>2</sub> into the plant) causing build up of O<sub>2</sub>
  - **RUBISCO** can bind to CO<sub>2</sub> or O<sub>2</sub> – each produces a different product
    - CO<sub>2</sub>: Produces glyceraldehyde 3-phosphate – photosynthesis
    - O<sub>2</sub>: Produces phosphoglycolate – photorespiration (big waste of plant energy)
  - ATP and NADPH are used to generate more ribulose 1,5 bisphosphate (Step 3)

### **EXAMPLE:** Photorespiration in plant cells

- **C4 plants** (corn, certain types of grasses) handle O<sub>2</sub> build up by physically separating carbon fixation reactions
  - Mesophyll cells – light-dependent reaction and fixation of CO<sub>2</sub> to malate molecule
  - Bundle sheath cells – CO<sub>2</sub> is released from malate and continues along the C3 Calvin cycle pathway
    - RUBISCO is isolated from accumulation of O<sub>2</sub> to prevent wasting energy on photorespiration

**EXAMPLE:** C4 photosynthesis pathway

- **CAM plants** (cacti) handle O<sub>2</sub> build up by differentially controlling CO<sub>2</sub> at different points in the day
  - At night, when it is cool the stroma is open
    - CO<sub>2</sub> is fixed using RUBISCO and the C3 pathways
  - In daytime, when it is hot the stroma is closed
    - CO<sub>2</sub> is fixed to malate and stored in a vacuole
    - When the stroma closes CO<sub>2</sub>-malates leaves the vacuole, is released and fixed by RUBISCO

**EXAMPLE:** Transition between day and night in CAM plants

### PRACTICE:

1. What is the function of RUBISCO in carbon fixation?
  - a. Catalyzes carbon fixation
  - b. Convert carbon into starch
  - c. Promoting gas exchange
  - d. Opening and closing the stroma
2. Why does the Calvin cycle require light?
  - a. Because light forms ATP through the light dependent reactions
  - b. Because light forms NADPH through the light dependent reactions
  - c. Because light forms  $\text{CO}_2$  through the light dependent reactions
  - d. Because light forms  $\text{O}_2$  through the light dependent reactions

3. How many molecules of  $\text{CO}_2$  are required to create one glyceraldehyde 3-phosphate?

- a. 1
- b. 2
- c. 3
- d. 4

4. True or False: RUBISCO only binds to  $\text{CO}_2$ .

- a. True
- b. False

5. Which of the following plants handles  $O_2$  buildup by physically separating RUBISCO from  $O_2$ ?
- a. C3 Plants
  - b. C4 Plants
  - c. CAM Plants
